

# Flexible Multinomial Logit Models with Preference Space and Willingness-to-Pay Space Utility Specifications in R: The **logitr** Package

John Paul Helveston  
George Washington University

---

## Abstract

In many applications of discrete choice models, modelers are interested in estimating consumer’s marginal “willingness-to-pay” (WTP) for different attributes. WTP can be computed by dividing the estimated parameters of a utility model in the preference space by the price parameter or by estimating a utility model in the WTP space. For homogeneous models, these two procedures generally produce the same estimates of WTP, but the same is not true for heterogeneous models where model parameters are assumed to follow a specific distribution. The **logitr** package was written to allow for flexible estimation of multinomial logit models with preference space and WTP space utility specifications. The package supports homogeneous multinomial logit (MNL) and heterogeneous mixed logit (MXL) models, including support for normal and log-normal parameter distributions. Since MXL models and models with WTP space utility specifications are non-convex, an option is included to run a multi-start optimization loop with random starting points in each iteration. The package also includes a market simulation function to estimate the expected market shares of a set of alternatives using an estimated model.

*Keywords:* multinomial logit, preference space, willingness-to-pay space, discrete choice, R.

---

## 1. Introduction

In many applications of discrete choice models, modelers are interested in estimating consumer’s marginal “willingness-to-pay” (WTP) for different attributes. WTP can be estimated in two ways:

1. Estimate a discrete choice model in the “preference space” where parameters have units of utility and then compute the WTP by dividing the parameters by the price parameter.
2. Estimate a discrete choice model in the “WTP space” where parameters have units of WTP.

While the two procedures generally produce the same estimates of WTP for homogeneous models, the same is not true for heterogeneous models where model parameters are assumed to follow a specific distribution, such as normal or log-normal (Train and Weeks 2005). For example, in a preference space specification, a normally distributed attribute parameter divided by a log-normally distributed price parameter produces a strange WTP distribution with large tails. In contrast, a WTP space specification allows the modeler to directly assume

WTP is normally distributed. The **logitr** package was developed to enable modelers to choose between these two utility spaces when estimating multinomial logit models.

## 2. The random utility model in two spaces

The random utility model is a well-established framework in many fields for estimating consumer preferences from observed consumer choices (Louviere, Hensher, and Swait 2000, Train (2009)). Random utility models assume that consumers choose the alternative  $j$  a set of alternatives that has the greatest utility  $u_j$ . Utility is a random variable that is modeled as  $u_j = v_j + \varepsilon_j$ , where  $v_j$  is the “observed utility” (a function of the observed attributes such that  $v_j = f(\mathbf{x}_j)$ ) and  $\varepsilon_j$  is a random variable representing the portion of utility unobservable to the modeler.

Adopting the same notation as in Helveston et al. (2018), consider the following utility model:

$$u_j^* = \boldsymbol{\beta}^{*'} \mathbf{x}_j - \alpha^* p_j + \varepsilon_j^*, \quad \varepsilon_j^* \sim \text{Gumbel} \left( 0, \sigma^2 \frac{\pi^2}{6} \right) \quad (1)$$

where  $\boldsymbol{\beta}^*$  is the vector of coefficients for non-price attributes  $\mathbf{x}_j$ ,  $\alpha^*$  is the coefficient for price  $p_j$ , and the error term,  $\varepsilon_j^*$ , is an IID random variable with a Gumbel extreme value distribution of mean zero and variance  $\sigma^2(\pi^2/6)$ . This model is not identified since there exists an infinite set of combinations of values for  $\boldsymbol{\beta}^*$ ,  $\alpha^*$ , and  $\sigma$  that produce the same choice probabilities. In order to specify an identifiable model, the modeler must normalize equation (1). One approach is to normalize the scale of the error term by dividing equation (1) by  $\sigma$ , producing the “preference space” utility specification:

$$\left( \frac{u_j^*}{\sigma} \right) = \left( \frac{\boldsymbol{\beta}^*}{\sigma} \right)' \mathbf{x}_j - \left( \frac{\alpha^*}{\sigma} \right) p_j + \left( \frac{\varepsilon_j^*}{\sigma} \right), \quad \left( \frac{\varepsilon_j^*}{\sigma} \right) \sim \text{Gumbel} \left( 0, \frac{\pi^2}{6} \right) \quad (2)$$

The typical preference space parameterization of the multinomial logit (MNL) model can then be written by rewriting equation (2) with  $u_j = (u_j^*/\sigma)$ ,  $\boldsymbol{\beta} = (\boldsymbol{\beta}^*/\sigma)$ ,  $\alpha = (\alpha^*/\sigma)$ , and  $\varepsilon_j = (\varepsilon_j^*/\sigma)$ :

$$u_j = \boldsymbol{\beta}' \mathbf{x}_j - \alpha p_j + \varepsilon_j \quad \varepsilon_j \sim \text{Gumbel} \left( 0, \frac{\pi^2}{6} \right) \quad (3)$$

The vector  $\boldsymbol{\beta}$  represents the marginal utility for changes in each non-price attribute, and  $\alpha$  represents the marginal utility obtained from price reductions. In addition, the coefficients  $\boldsymbol{\beta}$  and  $\alpha$  are measured in units of *utility*, which only has relative rather than absolute meaning.

The alternative normalization approach is to normalize equation (1) by  $\alpha^*$  instead of  $\sigma$ , producing the “willingness-to-pay (WTP) space” utility specification:

$$\left( \frac{u_j^*}{\alpha^*} \right) = \left( \frac{\boldsymbol{\beta}^*}{\alpha^*} \right)' \mathbf{x}_j - p_j + \left( \frac{\varepsilon_j^*}{\alpha^*} \right), \quad \left( \frac{\varepsilon_j^*}{\alpha^*} \right) \sim \text{Gumbel} \left( 0, \frac{\sigma^2}{(\alpha^*)^2} \frac{\pi^2}{6} \right) \quad (4)$$

Since the error term in equation is scaled by  $\lambda^2 = \sigma^2/(\alpha^*)^2$ , we can rewrite equation (4) by multiplying both sides by  $\lambda = (\alpha^*/\sigma)$  and renaming  $u_j = (\lambda u_j^*/\alpha^*)$ ,  $\boldsymbol{\omega} = (\boldsymbol{\beta}^*/\alpha^*)$ , and  $\varepsilon_j = (\lambda \varepsilon_j^*/\alpha^*)$ :

$$u_j = \lambda (\boldsymbol{\omega}' \mathbf{x}_j - p_j) + \varepsilon_j \quad \varepsilon_j \sim \text{Gumbel} \left( 0, \frac{\pi^2}{6} \right) \quad (5)$$

Here  $\omega$  represents the marginal WTP for changes in each non-price attribute, and  $\lambda$  represents the scale of the deterministic portion of utility relative to the standardized scale of the random error term.

The utility models in equations 3 and 5 represent the preference space and WTP space utility specifications, respectively. In equation 3, WTP is estimated as  $\beta/\hat{\alpha}$ ; in equation 5, WTP is simply  $\hat{\omega}$ .

### 3. Using the logitr package

#### 3.1. Installation

This package has not been uploaded to CRAN, but it can be directly installed from Github using the **devtools** library. The package also depends on the **nloptr** library.

First, make sure you have the **devtools** and **nloptr** libraries installed:

```
install.packages("devtools")
install.packages("nloptr")
```

Then load the **devtools** library and install the **logitr** package:

```
library("devtools")
install_github("jhelvy/logitr")
```

#### 3.2. Data format

The data must be arranged the following way:

1. The data must be a **data.frame** object.
2. Each row is an alternative from a choice observation. Each choice observation does not have to have the same number of alternatives.
3. Each column is a variable.
4. One column must identify **obsID** (the “observation ID”): a sequence of numbers that identifies each unique choice occasion. For example, if the first three choice occasions had 2 alternatives each, then the first 9 rows of the **obsID** variable would be 1,1,2,2,3,3.
5. One column must identify **choice**: a dummy variable that identifies which alternative was chosen (1=chosen, 0=not chosen).
6. For WTP space models, one column must identify **price**: a continuous variable of the price values.

An example of the ‘Yogurt’ data set from the **mlogit** package illustrates this format:

```
R> library('logitr')
R> data(yogurt)
R> head(yogurt, 12)
```

	id	obsID	choice	price	feat	brand	dannon	hiland	weight	yoplait
1	1	1	0	8.1	0	dannon	1	0	0	0
2	1	1	0	6.1	0	hiland	0	1	0	0
3	1	1	1	7.9	0	weight	0	0	1	0
4	1	1	0	10.8	0	yoplait	0	0	0	1
5	1	2	1	9.8	0	dannon	1	0	0	0
6	1	2	0	6.4	0	hiland	0	1	0	0
7	1	2	0	7.5	0	weight	0	0	1	0
8	1	2	0	10.8	0	yoplait	0	0	0	1
9	1	3	1	9.8	0	dannon	1	0	0	0
10	1	3	0	6.1	0	hiland	0	1	0	0
11	1	3	0	8.6	0	weight	0	0	1	0
12	1	3	0	10.8	0	yoplait	0	0	0	1

### 3.3. The `logitr()` function

The main model estimation function is the `logitr()` function:

```
R> model = logitr(data, choiceName, obsIDName, parNames, priceName=NULL,
R>               randPars=NULL, randPrice=NULL, modelSpace="pref",
R>               options=list(...))
```

The function returns a list of values, so assign the model output to a variable (e.g. `model`) to store the output values.

#### *Arguments*

Argument	Description	Default
<code>data</code>	The choice data, formatted as a <code>data.frame</code> object.	—
<code>choiceName</code>	The name of the column that identifies the <code>choice</code> variable.	—
<code>obsIDName</code>	The name of the column that identifies the <code>obsID</code> variable.	—
<code>parNames</code>	The names of the parameters to be estimated in the model. Must be the same as the column names in the <code>data</code> argument. For WTP space models, do not include <code>price</code> in <code>parNames</code> .	—
<code>priceName</code>	The name of the column that identifies the price variable. Only required for WTP space models.	NULL
<code>randPars</code>	A named vector whose names are the random parameters and values the distribution: 'n' for normal or 'ln' for log-normal.	NULL
<code>randPrice</code>	The random distribution for the price parameter: 'n' for normal or 'ln' for log-normal. Only used for WTP space MXL models.	NULL
<code>modelSpace</code>	Set to 'wtp' for WTP space models.	'pref'
<code>options</code>	A list of options.	—

*Options*

Argument	Description	Default
<code>numMultiStarts</code>	Number of times to run the optimization loop, each time starting from a different random starting point for each parameter between <code>startParBounds</code> . Recommended for non-convex models, such as WTP space models and MXL models.	1
<code>keepAllRuns</code>	Set to <code>TRUE</code> to keep all the model information for each multistart run. If <code>TRUE</code> , the <code>logitr()</code> function will return a list with two values: <code>models</code> (a list of each model), and <code>bestModel</code> (the model with the largest log-likelihood value).	<code>FALSE</code>
<code>startParBounds</code>	Set the <code>lower</code> and <code>upper</code> bounds for the starting parameters for each optimization run, which are generated by <code>runif(n, lower, upper)</code> .	<code>c(-1,1)</code>
<code>startVals</code>	A vector of values to be used as starting values for the optimization. Only used for the first run if <code>numMultiStarts &gt; 1</code> .	<code>NULL</code>
<code>useAnalyticGrad</code>	Set to <code>FALSE</code> to use numerically approximated gradients instead of analytic gradients during estimation (which is slower).	<code>TRUE</code>
<code>scaleInputs</code>	By default each variable in <code>data</code> is scaled to be between 0 and 1 before running the optimization routine because it usually helps with stability, especially if some of the variables have very large or very small values (e.g. $> 10^3$ or $< 10^{-3}$ ). Set to <code>FALSE</code> to turn this feature off.	<code>TRUE</code>
<code>standardDraws</code>	By default, a new set of standard normal draws are generated during each call to <code>logitr</code> (the same draws are used during each multistart too). The user can override those draws by providing a matrix of standard normal draws if desired.	<code>NULL</code>
<code>numDraws</code>	The number of draws to use for MXL models for the maximum simulated likelihood.	200
<code>drawType</code>	The type of draw to use for MXL models for the maximum simulated likelihood. Set to <code>'normal'</code> to use random normal draws or <code>'halton'</code> for Halton draws.	<code>'halton'</code>
<code>printLevel</code>	The print level of the <code>nloptr</code> optimization loop. Type <code>nloptr.print.options()</code> for more details.	0
<code>xtol_rel</code>	The relative <code>x</code> tolerance for the <code>nloptr</code> optimization loop. Type <code>nloptr.print.options()</code> for more details.	<code>1.0e-8</code>
<code>xtol_abs</code>	The absolute <code>x</code> tolerance for the <code>nloptr</code> optimization loop. Type <code>nloptr.print.options()</code> for more details.	<code>1.0e-8</code>
<code>ftol_rel</code>	The relative <code>f</code> tolerance for the <code>nloptr</code> optimization loop. Type <code>nloptr.print.options()</code> for more details.	<code>1.0e-8</code>

Argument	Description	Default
<code>ftol_abs</code>	The absolute <code>f</code> tolerance for the <code>nloptr</code> optimization loop. Type <code>nloptr.print.options()</code> for more details.	<code>1.0e-8</code>
<code>maxeval</code>	The maximum number of function evaluations for the <code>nloptr</code> optimization loop. Type <code>nloptr.print.options()</code> for more details.	<code>1000</code>

*Values*

Value	Description
<code>coef</code>	The model coefficients at convergence.
<code>standErrs</code>	The standard errors of the model coefficients at convergence.
<code>logLik</code>	The log-likelihood value at convergence.
<code>nullLogLik</code>	The null log-likelihood value (if all coefficients are 0).
<code>gradient</code>	The gradient of the log-likelihood at convergence.
<code>hessian</code>	The hessian of the log-likelihood at convergence.
<code>numObs</code>	The number of observations.
<code>numParams</code>	The number of model parameters.
<code>startPars</code>	The starting values used.
<code>multistartNumber</code>	The multistart run number for this model.
<code>time</code>	The user, system, and elapsed time to run the optimization.
<code>iterations</code>	The number of iterations until convergence.
<code>message</code>	A more informative message with the status of the optimization result.
<code>status</code>	An integer value with the status of the optimization (positive values are successes). Type <code>logitr.statusCodes()</code> for a detailed description.
<code>modelSpace</code>	The model space (' <code>pref</code> ' or ' <code>wtp</code> ').
<code>standardDraws</code>	The draws used during maximum simulated likelihood (for MXL models).
<code>randParSummary</code>	A summary of any random parameters (for MXL models).
<code>parSetup</code>	A summary of the distributional assumptions on each model parameter (" <code>f</code> "="fixed", " <code>n</code> "="normal distribution", " <code>ln</code> "="log-normal distribution").
<code>options</code>	A list of all the model options.

**3.4. Details about “parNames” argument:**

A structural assumption in the `logitr` package is that the deterministic part of the utility specification is linear in parameters:  $v_j = \beta' \mathbf{x}_j$  for preference space models, and  $v_j = \omega' \mathbf{x}_j$  for WTP space models. Accordingly, each parameter in the `parNames` argument must correspond to a variable in the data that is an additive part of  $v_j$ . For WTP space models, the `parNames` should only include the WTP parameters, and the `price` parameter is denoted by the separate

argument `priceName`. Here are several examples:

Space	Model	parNames	priceName
Preference	$u_j = \beta_1 price_j + \beta_2 size_j + \varepsilon_j$	<code>c('price', 'size')</code>	NULL
WTP	$u_j = \lambda_j(\beta_1 size_j - price_j) + \varepsilon_j$	<code>c('size')</code>	'price'

### 3.5. Using `summary()` with `logitr`

The `logitr` package includes a summary function that has several variations:

- For a single model run, it prints some summary information, including the model space, log-likelihood value at the solution, and a summary table of the model coefficients.
- For MXL models, the function also prints a summary of the random parameters.
- If the `keepAllRuns` option is set to `TRUE`, the function will print a summary of all the multistart runs followed by a summary of the best model (as determined by the largest log-likelihood value).

To understand the status code of any model, type `logitr.statusCodes()`, which prints a description of each status code from the `nloptr` optimization routine.

### 3.6. Computing and Comparing WTP

For models in the preference space, you can get a summary table of the implied WTP by using the `wtp()` function:

```
wtp(model, priceName)
```

To compare the WTP between two equivalent models in the preference space and WTP spaces, use the `wtpCompare()` function:

```
wtpCompare(prefSpaceModel, wtpSpaceModel, priceName)
```

### 3.7. Market Simulations

After estimating a model, often times modelers use the results to simulate the market shares of a particular set of market alternatives. This can be done using the `marketSimulation()` function. The simulation reports the expected market share as well as a confidence interval for each market alternative:

```
simulation = marketSimulation(model, market, priceName=NULL, alpha=0.025)
```

#### *Arguments*

Argument	Description	Default
<code>model</code>	A MNL or MXL model estimated using the <code>logitr</code> package.	–
<code>market</code>	A data frame of the market alternatives. Each row should be an alternative, and each column an attribute for which there is a corresponding coefficient in the estimated model.	–
<code>priceName</code>	The name of the column in the <code>market</code> that identifies price (only required for WTP space models).	NULL
<code>alpha</code>	The significance level for the confidence interval (e.g. 0.025 results in a 95% CI).	0.025

### 3.8. Citation Information

If you use this package for an analysis that is published, I would greatly appreciate it if you included a citation. You can get the citation information by typing this into R:

```
citation("logitr")
```

## 4. Examples

All examples use the `Yogurt` data set from Jain et al. (1994), reformatted for use in the `logitr` package. The data set contains 2,412 choice observations from a series of yogurt purchases by a panel of 100 households in Springfield, Missouri, over a roughly two-year period. The data were collected by optical scanners and contain information about the price, brand, and a “feature” variable, which identifies whether a newspaper advertisement was shown to the customer. There are four brands of yogurt: Yoplait, Dannon, Weight Watchers, and Hiland, with market shares of 34%, 40%, 23% and 3%, respectively.

In the utility models described below, the data variables are represented as follows:

Symbol	Variable
$p$	The price in US dollars.
$x_j^{\text{FEAT}}$	A dummy variable for whether the newspaper advertisement was shown to the customer.
$x_j^{\text{DANNON}}$	A dummy variable for the “Dannon” brand.
$x_j^{\text{HIGHLAND}}$	A dummy variable for the “Highland” brand.
$x_j^{\text{YOPLAIT}}$	A dummy variable for the “Yoplait” brand.

### 4.1. MNL model in the preference space

Estimate the following homogeneous multinomial logit model in the preference space:

$$u_j = \alpha p_j + \beta_1 x_j^{\text{FEAT}} + \beta_2 x_j^{\text{DANNON}} + \beta_3 x_j^{\text{HIGHLAND}} + \beta_4 x_j^{\text{YOPLAIT}} + \varepsilon_j \quad (6)$$

where the parameters  $\alpha$ ,  $\beta_1$ ,  $\beta_2$ ,  $\beta_3$ , and  $\beta_4$  have units of utility.

**Estimate the model:**

```
R> library("logitr")
R> data(yogurt)
R>
R> mnl.pref = logitr(
R>   data      = yogurt,
R>   choiceName = "choice",
R>   obsIDName  = "obsID",
R>   parNames   = c("price", "feat", "dannon", "hiland", "yoplait"))
```

**Print a summary of the results:**

```
R> summary(mnl.pref)
```

```

Since WTP space models are non-convex, you cannot be certain that the model reached a global solution, even when using a multistart. However, since the preference space model is convex, you can compute the WTP from the preference space model and compare it against the results from the WTP space model. If the WTP values and log-likelihood values from the two model spaces are equal, then the WTP space model is likely at a global solution. To compare the WTP and log-likelihood values between the preference space and WTP space models, use the `wtpCompare()` function:

```
R> wtpCompare(mnl.pref, mnl.wtp, priceName='price')
```

```
**Using results for the best model from the model.wtp multistart**
```

	pref	wtp	difference
lambda	0.366584	0.3665844	3.90e-07
feat	1.340569	1.3405709	1.93e-06
dannon	1.749081	1.7490786	-2.42e-06
hiland	-8.386651	-8.3866509	7.00e-08
yoplait	3.752907	3.7529020	-5.04e-06
logLik	-2656.887878	-2656.8878779	0.00e+00
